Tutorial: BwUniCluster 3.0/HoreKa

Hot Radiation Room (parallel)

In this tutorial we will learn about the simulation of radiative heat transfer in OpenFOAM on multiple cores by submitting a parallel job. We will do it using the example hotRadiationRoom from the series of built-in OpenFOAM tutorials.

1. Tutorial Case

First, we should copy the tutorial case from the FOAM_TUTORIALS directory and paste it into our workspace (the current directory is denoted by a point):

```
$> cd <workdir>
$> module purge
$> module load cae/openfoam/v2112
$> source $FOAM_INIT
$> cp -R $FOAM_TUTORIALS/heatTransfer/buoyantSimpleFoam/hotRadiationRoom/ .
$> cp $FOAM_TUTORIALS/multiphase/compressibleInterFoam/laminar/depthCharge3D/system/decomposeParDict hotRadiationRoom/system
```

Note: The last command copies the dictionary used for domain decomposition from another tutorial. We will modify it for our example.

2. Creating the Mesh

The mesh in the hotRadiationRoom tutorial represents a 10m x 6m x 2m room equipped with a heat source in the corner of its floor.

In order to create the mesh using data from the blockMeshDict-file, we will use the following command:

```
$> cd hotRadiationRoom
$> blockMesh
```

Or, better - as it allows to keep the statistics of the grid in a dat-file:

```
$> blockMesh > screen_output_blockmesh.dat
```

Apart from describing the basic structure of the mesh, the blockMeshDict file also defines boundaries, known as patches, for which later on special boundary conditions will be set. In our case these areas are: floor, ceiling, fixedWalls and box. To view this text-file, you can use the command:

```
$> more system/blockMeshDict
```

The mesh is shown in Fig. 1. Figures 2, 3 and 4 show the different boundary patches.

Fig.1 The hotRadiationRoom mesh created using blockMesh

Fig.2 Boundary patch "fixedWalls"

Fig.3 Boundary patch "ceiling"

Fig.4 Boundary patch "floor"

Fig.4 Boundary patch "box"

In this tutorial there will be a heat source with the temperature of 500 K in the box patch:

Fig.5 The heat source in the box patch

//

Note!: On HoreKa use for the name of the partition `dev_cpuonly`. On `bwUniCluster3.0` use `dev_cpu`. Names of partitions can change frequently, always visit the corresponding web-page or use the command “`sinfo_t_idle`”.

We can then submit the job using the name of the job-file with the following command:

```
$> sbatch job_submit_dev_parallel_uc3.sh
```

After the simulation has been completed, we can combine the results from different cores (processor* -directories) into one directory using the command:

```
$> reconstructPar
```

We can also continue without reconstructing. In that case we will be able to visualize results from different processors (decomposed case) as well as the reconstructed case in Paraview.

Note: Following our own recommendations - we did not use the files `Allrun` and `Allclean`.

3. Results

After the simulation has been completed we can **download the results** onto our personal computer and visualize them in Paraview. This is **the recommended way for visualizing results** with small- or medium-sized grids which is the most common case.

We can now examine the steady state of the heat transfer in the room which has been achieved after 935 iterations. The following images depict the central plane of the control room from the top-down view with the box patch located in the bottom left corner.

Fig.6 Temperature from the horizontal (top-down) view [K]

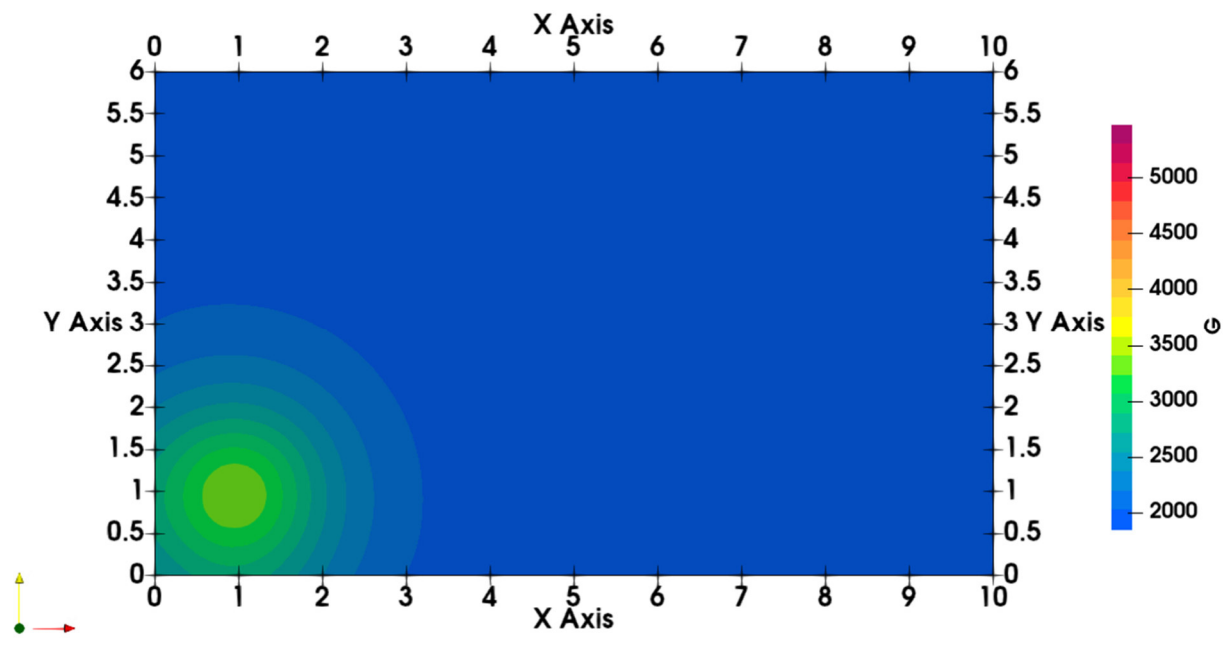

Fig.7 Radiation Intensity „G” from the horizontal (top-down) view [W/m²]

Fig.8 Velocity vectors in the top-down view [m/s]

Another place worth looking at is the Y-normal plane going through the box patch:

Fig.9 Temperature in a vertical plane [K]

Fig.10 Radiation Intensity „G” in a vertical plain [W/m³]

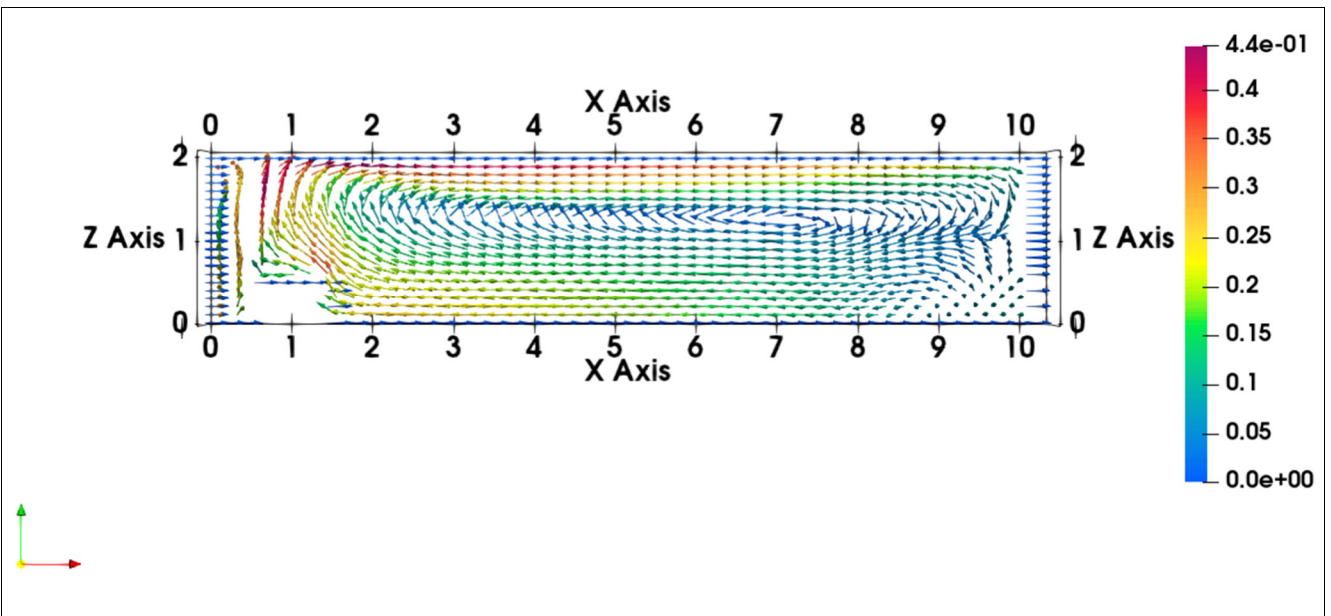

Fig.11 Velocity in a vertical plane [m/s]

Fig.12 Radiative heat flux „qr” in a vertical plane [W/m²]

Legend

a	Absorption coefficient	[1/m]
alphat	Turbulent thermal diffusivity	[kg/(m.s)]
epsilon	Turbulent kinetic energy dissipation rate	[J/(kg.s)] or [m ² /s ³]
G	Incident radiation intensity	[W/m ²]
qr	Radiative heat flux	[W/m ²]
phi	Mass flow	[kg/s]
k	Turbulent kinetic energy	[J/kg] or [m ² /s ²]
nut	Turbulent viscosity	[m ² /s]

Note: The names in the leftmost column are the variables in the 0 directory.
